- Threat Model
- Goals
- TUX : Trusted Update on Linux Kernel
- Experiments
- Discussion
- Conclusion

Intro

Security vulnerabilities are prevalent.

- Tons of CVEs
- Meltdown & Spectre

Lots of security updates!

Less attention was given to the changing integrity after the updates are conducted.

Intro

Maintain Integrity

Verifying the system by checking whether there are any malicious modification.

Security Update

countermeasure vulnerabilities by modifying the system.

Can modern solutions distinguish between updates and malicious modifications?

Is the integrity being managed according to the updates?

Intel Trusted Execution Technology(TXT)

Intel's Measured / Verified boot technology

<u>tboot</u>

- Grub bootloader module
- Measure and verify integrity using DRTM

Launch control policy (LCP)

- Known good integrity values for certain booting stages
- Used to verify the integrity of the booting
- Also needs to be updated when the system is updated

Does not measure/verify Grub environment (e.g., Grub commands)

Open Cloud Integrity Technology (CIT)

Intel's remote attestation solution Validate TPM measurements from

the remote server

Known-good values

- Stored in the Open CIT server
- Imported from the local systems

Local updates are not transparent

- Open CIT cannot monitor updates conducted from the local systems
- If local system is updated, remote attestation fails

UEFI secure boot

UEFI BIOS's Verified boot component

- Verify integrity using the key stored in the firmware DB
- Booting components must be digitally signed

Updating is easy for Secure boot

- Sign updated binary and deploy
- Receive update and install

Not suitable for Linux environment

- Does not approve Grub bootloader
- Cannot verify Grub commands

No TPM measurements

MOSL Mobile OS Laboratory

Keys used in UEFI secure boot

INIVERSITY

Threats!

Subverting Open CIT

- Occurs because the local updates are not transparent to the Open CIT
- Assumption: Attacker can update OS and perform measured boot

(OOK UNIVERSITY

Threats!

Circumventing verified boot

- Rootkit
 - Breaking Hardware-Enforced Security with Hypervisors (Black hat USA 2016)
- Attacker can modify Grub commands even though the Secure boot is on
- TXT and Secureboot lack of Grub command verification

Goals!

To maintain integrity properly...

- 1. Remote attestation must manage local updates transparently.
- 2. Maintain whitelist according to conducted updates and perform remote attestation using the up-to-date whites list.
- 3. Perform thorough measured / verified booting including Grub.

TUX Code can be found at... https://github.com/suhho1993/TUX.git

MOSL Mobile OS Laboratory

Trusted Platform Module (TPM)

Provide TEE for integrity measurement

Tamper-proof device

Practically used in measured boot

Platform Configuration Registers (PCRs)

- TPM measures integrity using extend operation.
 - $PCR_{new} = Hash(PCR_{old} \oplus Hash(Data))$
 - Form Chain-of-Trust to verify the system configuration
 - Measure entire booting process with extend operation

TPM Architecture

Shim and Grub

Shim

- 1stage bootloader to support UEFI secure boot
- Can be verified by the UEFI secure boot
 - Signed with MS's firmware key
- Shim verifies and execute Grub
- Verification using firmware keys
 - Shim_lock verification

Grub

• CoreOS and other GRUBs support measured boot using TPM v2.0

TUX server is the maintainer/administrator of the updates.

TUX only verifies integrity of the Linux Booting process.

TUX server is trusted and safe.

TUX owner holds manifest of specific booting process of each managed machine.

All managed machines hold TUX owner's public key.

TUX Architecture

DANKOOK UNIVERSITY

Integrity Manager

Integrity management / kernel update component

- Located at the Open CIT server
- Consists of Trusted repository, Whitelist updater, PCR-signed Kernel generator

Trusted repository

- Update repository
- Stores kernel binaries and manifests for the update
- Provide binaries to generate new whitelist.

Whitelist updater

- Calculate new integrity value and update the whitelist
- Calculate t-PCR
- PCR-signed kernel generator
 - Generate PCR-signed kernel

Integrity manager

Kernel update using TUX

ANKOOK UNIVERSITY

Remote attestation with TUX

With Integrity Manger, TUX...

- Manage local updates transparently (Goal 1)
- Prevent remote attestation failure after updates
- Perform remote attestation with updated whitelist (Goal 2)

A. Remote Attestation

PCR-Signed Kernel

t-PCR

• Calculated known-good value by extending entire booting process

PCR-signed Kernel

- Use t-PCR value to sign the kernel binary instead of digested hash
- Signed with TUX owner's private key
- Used to verify integrity during the booting

Trusted Secure boot (TS-Boot)

Combination of UEFI secure boot, Shim, and CoreOS Grub

• Perform robust measured/verified boot

Linux friendly

Binary verification using the firmware key

• Shim_lock verification

Thorough measurement / verification of the booting process

- Including Grub commands and modules
- PCR-verification

PCR-Verification

- Verifies the integrity of the entire booting process on runtime
- Extend measurement of every booting process using the PCR12
- Execute kernel using linuxefi function
 - Pass the kernel to Shim using shim_lock_verification
- Compare PCR12 with t-PCR stored in the kernel signature
- Any changes can be detected

Trusted Secure Boot (TS-Boot)

With TS-Boot, TUX...

Measure / verify the integrity of the entire booting process including Grub command and modules (Goal 3)

Boot-time integrity verification

Experiment

• TPM measurement

MOSL Mobile OS Laboratory

Demo

Discussion

Roll-back and multiple kernel support

• Roll-back attack can be detected!

TUX owner's Key is Safe

• Open CIT server is safe / Firmware is safe

TUX may be applicable to environment other than desktop or server

SRTM or DRTM?

Integrity changes when update is conducted, and thus, it should be properly managed along with updates.

TUX...

Extends Open CIT to transparently mange local updates

Remote attestation with up-to-date whitelist

Thorough integrity measurement, including Grub commands and modules

Robust integrity verification with PCR-verification

Thank you.

Any Questions?
